UNITED STATES DEPARTMENT OF AGRICULTURE UC 1 1934 & Bureau of Entomology and Plant Quarantine & Department of Agriculture Washington, D.C.

BRARY

Acrelopments in the Japanese beetle Situation October 20, 1934.

The accompanying statement summarizes the results of the season's scouting to obtain timely information as to the distribution of the Japanese beetle. To it is attached, as part of the record, the trapping report by States; also comparative data, where available, of beetle catches in this and previous seasons.

The work of the season indicates that with the exception of three localities the beetle has not become established in any place outside the present regulated areas. The capture of a few beetles at certain points outside the regulated area does not mean that an infestation is established, and extension of the quarantine to cover such localities may safely be postponed, as in previous years. In the three places where infestation is established (St. Louis, Mo., Indianapolis, Ind., and Charlottesville, Va.), extensive control programs are under way which, with other safeguards, will be adequate to prevent spread from these sections. There is, therefore, no need for the extension of the regulated area and no quarantine hearing will be held this year to consider extension of the area or modification of the regulations. The accompanying statement will serve the same purpose as the report usually given at quarantine hearings by making available to State quarantine officers and others the latest information as to the distribution of this insect.

LEE A. STRONG,

Chief of Bureau.

DEVELOPMENTS IN THE JAPANESE BEETLE SITUATION DURING 1934

The most outstanding first-record find of the Japanese beetle at a point remote from the infested areas is that disclosed at St. Louis, Mo., where beetles were collected in such numbers as to indicate an established infestation. Another first-record find consisted of 17 beetles caught at Indianapolis, Ind., in a residential section of the city at some distance from a railroad line. This infestation probably resulted from illegal transportation of infested plant material. The infestation at Charlottesville, Va., can probably be accounted for in the same way. Beetles were first found at Charlottesville in 1932. This year 60 beetles were trapped in that city. The locations at which were trapped 6 beetles in Chicago, Ill., and 1 beetle in East St. Louis, Ill., point to the probability of these having been transported from the heavily infested sections of New Jersey or Pennsylvania via rail in refrigerator cars containing agricultural products not ordinarily subject to infestation.

Funds were available only for trapping to determine spread in those States immediately adjacent to known infested territory. Supplementing the State surveys in nonregulated territory in Maine, New York, Pennsylvania, Ohio, West Virginia, Virginia, and Maryland, traps were operated to check previously determined infestations in Detroit, Mich., St. Louis, Mo., and Greenville, S.C., and to determine the presence of the insect in Chicago and East St. Louis, Ill., and a few selected cities in Indiana. The season's trapping program began in Virginia on June 18. Trap distribution progressed northward, following the dates . of probable beetle emergence. The latest traps set were those placed in Maine. Except in cities where continued catches were being made, most of the traps were lifted after a 30-day period of operation. Final lifting of the late-operated traps in Maine was accomplished by September 21. Prior to this season's use, the traps were reconditioned and coated with aluminum paint. Since this protective coating weathered much better than the green and white enamel combination used previously, the traps, at the end of this season's work, were stored in municipal and county-owned buildings from which they may be readily distributed to adjacent territory next season. Curtailment of funds allowed the operation of only 31,000 of the project's supply of 56,000 traps.

The St. Louis infestation is now known to have existed since 1932, but the section involved was not surveyed because the presence of the insect in the city was not reported to this Bureau until early in 1934. Approximately 2,600 traps were concentrated in all likely infested sections from June 19 to August 25 of this year, with the resulting capture of 1,351 beetles. Funds recently made available by executive order have enabled the Bureau to start immediate application of thorough control measures in all infested sections of St. Louis. This work was begun on September 26 and is still in progress. Approximately 250 tons of lead arsenate are available for treating all of the 117 infested blocks at the rate of 1,000 pounds per acre. This is the largest control program ever undertaken at an

- 6 -

isolated infestation. Laborers to assist in applying the spray are being supplied by the local relief administration. The city fire department is assisting through the loan of hose lines. State and city officials are actively cooperating with the Bureau in this control work. Scouting of nursery and greenhouse establishments within a 10-mile radius of St.Louis gave negative results. A State quarantine on the movement of host material from infested sections will also be enforced.

It is also anticipated that lead arsenate will be applied to the limited sections found infested in Indianapolis, Ind., and in Charlottes-ville, Va.

When beetles were first found in Erie, Pa., in the summer of 1931, 170 specimens were collected. Following the capture of 282 beetles in 1932, all infested sections were given heavy applications of arsenate of lead to render the soil toxic to the beetle in the larval stage. In 1935, 167 beetles were caught in the city, but only 10 were found in the previously infested blocks. In a single block where 200 beetles had been captured the previous year, only 6 specimens were caught. As new infestations were determined outside the treated sections, additional poison was applied. This summer, with a still larger concentration of traps, only 114 beetles were captured. Forty-three of this total were survivors of infestations discovered in 1933 and first treated in the fall of that year. The remainder represents spread not previously determined. The significant feature of the control work in Erie is that intensive trapping in the older infested section of over 44 acres, where the soil has been poisoned for a period of 2 or more years, has disclosed only 3 beetles emerging from the entire area. This apparently progressive reduction in beetle population in a residential district affording favorable environment for rapid multiplication of the pest and difficult conditions for thoroughly treating every square foot of soil in which the insect might overwinter, is very encouraging from a control standpoint. Continuing the intensive eradication measures of previous years in Erie, the sections surrounding infestations found this year in unpoisoned areas were treated with lead arsenate at the rate of 1,000 pounds per acre. This treatment, involving the application of the soil insecticide to 6.6 acres, was accomplished between September 10 and 17, immediately after the traps were lifted for the season.

X

(11)

Although Waterville, Maine, was included within the regulated zone in an extension of territory effective as a result of the spread determined in 1933, trapping was repeated there again this year to learn whether the past winter's record-breaking subzero weather had killed off the overwintering grub population. Instead of 204 traps being operated for 30 days, as in 1933, this year 300 traps were operated for 40 days; and, whereas last year 139 beetles were trapped, this year's capture increased to 299. Apparently the soil temperature at a depth of 6 inches or more did not decline sufficiently to affect larval survival.

Under a campaign initiated by the New Jersey State Board of Agriculture, 510 large-sized Japanese beetle traps were sold to individuals throughout the State and to other purchasers in Norfolk and Richmond, Va., West Grove and Allentown, Pa., Bronxville, N.Y., and

Stamford, Conn. The type of trap sold was one not available through commercial channels. By disposing of them at cost, the committee was able to retail the traps at \$1.50 each.

Dense flight of the beetle in heavily infested sections occurred this year approximately 10 days to 2 weeks in advance of the insect's customary maximum appearance. By July 4, in densely infested sections of southern New Jersey, beetles had balled on early apples, and browning of the foliage of badly devoured trees was plainly evident from a distance. By July 10 the foliage of many trees was completely skeletonized in the Shiloh section. Beetle activity reached its peak by the middle of July. The adults rapidly diminished in numbers after the first week in August.

The wavelike manner in which the beetle theoretically builds up and diminishes has not materialized in southern New Jersey. In this heavily infested agricultural area, sections that for years have been subject to intensive beetle damage are still holding their maximum populations. For three consecutive years early maturing apples in certain orchards have been rendered unsalable by beetle feeding. In the Philadelphia waterfront district in 1933, the expected heavy flight of the adult did not occur, indicating that the insect was on the wane in the business section of the city. This summer the insect resumed its heavy flight in the wharf and market districts, contradicting previous conclusions that the population might have decreased permanently. This year's adult flight lasted for nearly 5 weeks, from July 11 to August 13.

Beetle feeding in one block of 1,200 Yellow Transparent apples located in southern New Jersey was responsible for almost complete destruction of the crop. In 1933, 3,600 bushels were harvested from the orchard. This year but 36 bushels could be picked. Other severe commercial damage was evident throughout the densely infested sections.

Flotations of adult beetles in Delaware Bay, Raritan Bay, and the Atlantic Ocean were again observed, but not to the same extent as occurred last year. The flotation from New Jersey to the Delaware shore on Delaware Bay was most pronounced in mid-July. Beetles were washed up on the beaches of Long Island on August 10.

Nursery and greenhouse scouting this season resulted in the finding of adult beetles on a larger number of theretofore uninfested premises than were determined as infested in 1933. This season, infestations were found for the first time on 64 classified establishments, as compared with first-record finds on 33 such premises the preceding summer. Beetles have been found on the premises of over 80 percent of the nearly 400 classified establishments in New Jersey. This condition is a result of natural spread of the insect and expansion of its area of continuous distribution by about 900 square miles. Among 2,326 nurseries and greenhouses now fulfilling the quarantine requirements for classification, 528 are infested and the owners are obliged to grow their stock under beetle-proof conditions, and either to free it from soil or fumigate it before shipping to noninfested territory.

As in 1933, green beans were again shipped in large quantities to drought-stricken Midwestern markets from the bean-growing sections in southern New Jersey, in Morrisville and Bustleton, Pa., surrounding Baltimore, Md., and on the Eastern Shores of Maryland and Virginia. All beans shipped under certification from these areas were run through cylindrical inspection machines to rid them of beetles. Thousands of beetles were thus prevented from moving to noninfested States.

Evidence that adult beetles were flying into refrigerator cars while the cars were being loaded with certified beans, led to a temporary suspension of such shipments from Cedarville, N.J., from July 12 to 16. Shipping was resumed after beetle-proof enclosures had been constructed, under which inspected beans were loaded directly into refrigerator cars. Prior to loading, each car was searched for beetles, after which the side and ice bunker doors were kept closed or adequately screened.

From the knowledge gained as a result of the season's observations of accidental adult infestation of iced and uniced refrigerator cars loaded in the area of heavy flight, the Bureau is in a position at the first sign of such a flight next season to impose effective protective measures to prevent the entrance of the flying beetles into cars destined to distant markets.

From the accompanying list detailing the negative and positive results of this season's trapping activities, it will be noted that additional catches were recorded in 5 cities in Maine; in 58 Maryland communities, both inside and outside the regulated zone; in Detroit, Mich., where a few beetles have been trapped each year since 1932; in 9 New York cities; in 6 localities in Ohio; at Erie, Pa., where an infestation was first determined in 1931; in 6 cities in Virginia; and at 7 points in West Virginia. Traps set in Greenville, S.C., in an effort to pick up additional beetles at the site where 2 beetles were collected by hand, failed to catch any further specimens. Practically all of the few firstrecord infestations found in these States consisted of a few beetles each. None of them clearly pointed to an established infestation. The remaining infestations were largely survivors of known incipient infestations which successive years! trappings have shown not to have built up. There is also attached a supplementary list showing comparative results of trap activities as carried on in successive years in important communities both within and outside the present regulated zone.
